CHAPTER 1

About

The **niveristand** package contains an API (Application Programming Interface) that interacts with NI VeriStand systems. The package is implemented in Python. NI created and supports this package.

CHAPTER 2

Requirements

niveristand 0.9 has the following requirements:

- NI VeriStand 2018 running on the same system as the Python code.
- 64-bit version of Windows 10/8.1/7
- CPython 2.7 or 3.5+

To install **niveristand**, use one of the following methods:

1. **pip**:

```
$ python -m pip install niveristand
```

2. **easy_install** from **setuptools**:

```
$ python -m easy_install niveristand
```

3. Download the project source and run the following script:

```
$ python setup.py install
```

CHAPTER 4

Usage

Refer to *Basic Examples* for detailed information on how to write a Python real-time sequence.

CHAPTER 5

Support / Feedback

The **niveristand** package is supported by NI. For support for **niveristand**, open a request through the NI support portal at ni.com.

CHAPTER 6

Bugs / Feature Requests

To report a bug or submit a feature request, please use the [GitHub issues page](#).

CHAPTER 7

Documentation

To view the documentation, visit the [NI VeriStand Python Documentation Page](#).

CHAPTER 8

Additional Documentation

Refer to the [NI VeriStand Help](#) for detailed information on setting up a system and running real-time test scenarios.

NI VeriStand Help installs only with the full version of NI VeriStand.

niveristand is licensed under an MIT-style license (see [LICENSE](#)). Other incorporated projects may be licensed under different licenses. All licenses allow for non-commercial and commercial use.

9.1 Getting Started

9.1.1 Features

niveristand allows you to:

- Convert Python functions into NI VeriStand real-time (RT) sequences that are compatible with the NI VeriStand engine and Stimulus Profile Editor and save the converted Python functions to a file.
- Run test sequences in two different modes:
 - **Deterministic Mode** Deploys a real-time sequence to a running NI VeriStand system and executes the sequence in real-time.
 - **Python Mode** Runs a test sequence from a host machine that communicates with an NI VeriStand system through the Gateway. Python mode emulates the behavior of Deterministic mode. Python mode is useful in the following cases:
 - * You need to debug your real-time sequence.
 - * You want to take full advantage of the Python ecosystem.

9.1.2 Installation

To install **niveristand**, use one of the following methods:

1. `pip`:

```
$ python -m pip install niveristand
```

2. `easy_install` from `setuptools`:

```
$ python -m easy_install niveristand
```

3. Download the project source and run the following script:

```
$ python setup.py install
```

9.1.3 Usage

Refer to *Basic Examples* for detailed information on how to write a Python real-time sequence.

9.2 Examples

9.2.1 Basic Examples

Writing a sequence

A Python real-time sequence is a Python function decorated with the `niveristand.nivs_rt_sequence` decorator. For example, the following sequence calls a function and checks the result.

```
1 @nivs_rt_sequence
2 def call_add_two_numbers_test():
3     result = DoubleValue(0)
4     result.value = add_two_numbers(1, 2)
5     if result.value != 3:
6         generate_error(-100, "Unexpected result", ErrorAction.
↳ContinueSequenceExecution)
```

The function also takes in some parameters. You must define parameters using the `niveristand.NivsParam` decorator.

```
1 @NivsParam('x', DoubleValue(0), NivsParam.BY_VALUE)
2 @NivsParam('y', DoubleValue(0), NivsParam.BY_VALUE)
3 @nivs_rt_sequence
4 def add_two_numbers(x, y):
5     result = DoubleValue(0)
6     # There is an intentional mistake here. It multiplies when the function_
↳implies it adds.
7     result.value = x.value * y.value
8     return result.value
```

You can now run the test just like any other Python function. You can run it non-deterministically, as in the following example:

```

1  try:
2      call_add_two_numbers_test()
3  except RunError as run_error:
4      print("Something Non-deterministic went wrong:" + str(run_error))
5

```

Or, you can run the test deterministically on the VeriStand engine connected to your system.

```

1  try:
2      reallimesequencetools.run_py_as_rtseq(call_add_two_numbers_test)
3  except RunError as run_error:
4      print("Something Deterministic went wrong:" + str(run_error))

```

Combining the legacy API with real-time sequences

To create a fully-automated test environment, you can mix the *Legacy API* with Python real-time sequences.

```

1  import os
2  from examples.engine_demo.engine_demo_basic import run_engine_demo
3  from niveristand import run_py_as_rtseq
4  from niveristand.errors import RunError
5  from niveristand.legacy import NIVeriStand
6
7
8  def mix_legacy_and_rtseq_run():
9      """Combines the legacy API with Python real-time sequences to run a
10     ↪deterministic test."""
11     # Ensures NI VeriStand is running.
12     NIVeriStand.LaunchNIVeriStand()
13     # Uses the ClientAPI interface to get a reference to Workspace2
14     workspace = NIVeriStand.Workspace2("localhost")
15     engine_demo_path = os.path.join(os.path.expanduser("~"), 'Documents',
16     ↪'National Instruments', 'VeriStand 2018',
17     ↪'Examples', 'Stimulus Profile', 'Engine_
18     ↪Demo', 'Engine Demo.nivssdf')
19     # Deploys the system definition.
20     workspace.ConnectToSystem(engine_demo_path, True, 60000)
21     try:
22         # Uses Python real-time sequences to run a test.
23         run_py_as_rtseq(run_engine_demo)
24         print("Test Success")
25     except RunError as e:
26         print("Test Failed: %d - %s" % (str(e.error.error_code), e.error.
27     ↪message))
28     finally:
29         # You can now disconnect from the system, so the next test can run.
30         workspace.DisconnectFromSystem('', True)

```

(continues on next page)

(continued from previous page)

```

28
29 if __name__ == '__main__':
30     mix_legacy_and_rtseq_run()

```

Array operations example

```

1 @nivs_rt_sequence
2 def array_operations():
3     """
4     Shows operations you can perform with array data types in a real-time_
↪sequence.
5
6     An array can hold multiple values of the same data type. You cannot have_
↪arrays of arrays.
7     Use arrays to pass buffers of data for playback or storage.
8
9     Returns:
10        float: sum of all values in the array.
11
12    """
13    var = DoubleValue(0)
14    arr_size = I64Value(0)
15    array = DoubleValueArray([0, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100])
16
17    # Indexes a value out of an array.
18    var.value = array[4].value + 100
19    # Updates a value in an array.
20    array[2].value = 6.0
21    # Gets the size of an array.
22    arr_size.value = arraysize(array)
23    # Loops over each element of an array. Each time the loop iterates a_
↪value from the array is copied into x.
24    var.value = 0.0
25    for x in array:
26        var.value += x
27    return var.value

```

Measuring elapsed time example

```

1 @nivs_rt_sequence
2 def measure_elapsed_time():
3     """
4     Shows different ways to measure elapsed time in a sequence.
5
6     You can measure time in milliseconds, microseconds, or seconds.
7
8     Returns:
9         int: time, in milliseconds, it took to run this sequence.

```

(continues on next page)

(continued from previous page)

```

10
11     """
12     seqtime_timer = DoubleValue(0)
13     seqtime_us_timer = I64Value(0)
14     tick_ms_timer = I64Value(0)
15     tick_us_timer = I64Value(0)
16
17     # The following steps demonstrate different ways you can capture an
18     ↪initial timestamp:
19     seqtime_timer.value = seqtime()
20     seqtime_us_timer.value = seqtimeus()
21     tick_ms_timer.value = tickcountms()
22     tick_us_timer.value = tickcountus()
23
24     # Simulates work to time.
25     while iteration() < 1000:
26         nivs_yield()
27
28     # Measures the elapsed time by subtracting the initial timestamp from the
29     ↪current time.
30     seqtime_timer.value = seqtime() - seqtime_timer.value
31     seqtime_us_timer.value = seqtimeus() - seqtime_us_timer.value
32     tick_ms_timer.value = tickcountms() - tick_ms_timer.value
33     tick_us_timer.value = tickcountus() - tick_us_timer.value
34
35     return tick_ms_timer.value

```

State machine

```

1 @nivs_rt_sequence
2 def state_machine_example():
3     state = I32Value(0)
4     iters = I32Value(0)

9.3 API Reference

9.3.1 Decorators

`@niveristand.nivs_rt_sequence`

Marks a function as an RT sequence. You must mark a function as *nivs_rt_sequence* to run it deterministically with *run_py_as_rtseq*.

class `niveristand.NivsParam`(*param_name*, *default_elem*, *by_value*)

Describes a parameter passed down to a function.

Parameters

- **param_name** (*str*) – Name of the parameter as it is found in the function definition.
- **default_elem** – Default value and type. Refer to *NI VeriStand Data types* for valid values.
- **by_value** (*bool*) – Specifies whether to pass a parameter by value or by reference. Set to True to pass by value. Set to False to pass by reference. Refer to *NivsParam.BY_REF* or *NivsParam.BY_VALUE* for details.

BY_REF = False

Passes a parameter by reference. Allows the called function to modify the value.

BY_VALUE = True

Passes a parameter by value. Creates a copy of the caller's value for use inside the function.

9.3.2 Client API

NI VeriStand Data types

`niveristand.clientapi._datatypes.rtprimitives.DataType`

Real-Time Sequence APIs

Stimulus Profile APIs

9.3.3 Errors

class niveristand.errors.VeristandError

The base class for all VeriStandErrors.

Note: This class generates a *VeristandError* if a more specific error cannot be determined.

class niveristand.errors.TranslateError

Bases: *niveristand.errors.VeristandError*

Raised if a Python function fails to translate to a VeriStand real-time sequence.

class niveristand.errors.SequenceError(*error_code, message, error_action*)

Raised by `generate_error` to report a sequence failure.

inner_error

Returns the error generated before the most recent error, if any, or *None*.

Returns the previous error generated by this sequence.

Return type *SequenceError*

Real-time sequences report only the last error the sequence generates. If you want to see a list of all the inner errors, use *RunError.get_all_errors*.

is_fatal

Returns whether or not any error causes the sequence to stop.

Returns True if the error is `ErrorAction.AbortSequence` or `ErrorAction.StopSequence`, false if the error is `ErrorAction.ContinueSequenceExecution`.

Return type bool

should_raise

Determines whether or not this error raises an exception.

Returns False if the error is `ErrorAction.ContinueSequenceExecution` with an error code of 0. Otherwise, this function returns True.

Return type bool

class niveristand.errors.RunError(*error*)

Bases: *niveristand.errors.VeristandError*

Raised at the end of execution if an RT sequence called `generate_error`.

get_all_errors()

Generates a list of all errors reported during execution.

Returns all errors generated during execution.

Return type List(*SequenceError*)

class `niveristand.errors.RunFailedError` (*error*)

Bases: `niveristand.errors.RunError`

Raised by `run_py_as_rtseq` to report that the sequence failed.

This error is raised when a real-time sequence executes successfully, but `generate_error` was called with `ErrorAction.ContinueSequenceExecution`.

class `niveristand.errors.RunAbortedError` (*error*)

Bases: `niveristand.errors.RunError`

Raised by `run_py_as_rtseq` to report that the sequence failed.

This error is raised when a real-time sequence executes successfully, but `generate_error` was called with `ErrorAction.StopSequence` or `ErrorAction.AbortSequence`.

9.3.4 Library

9.3.5 Real-Time Sequence Tools

`niveristand.realtimesequencetools.run_py_as_rtseq` (*toplevelfunc*, *rt-seq_params={}*)

Runs a Python function as an RT sequence in the VeriStand Engine.

Parameters

- **toplevelfunc** – the Python function to run.
- **rtseq_params** (`Dict[str, niveristand.clientapi._datatypes.rtpimitives.DoubleValue]`) – the parameters to be passed to the RT sequence.

Returns The numeric value returned by the real-time sequence execution.

Return type `Union[float, None]`

Raises

- `TranslateError` – if the function is not successfully translated.
- `RunAbortedError` – if this function calls `generate_error` with an action of Abort or Stop.
- `RunFailedError` – if this function calls `generate_error` with a Continue action.

`niveristand.realtimesequencetools.save_py_as_rtseq` (*toplevelfunc*, *dest_folder*)

Saves a Python function as an RT sequence that is compatible with the Stimulus Profile Editor.

Parameters

- **toplevelfunc** – the Python function you want to save.
- **dest_folder[str]** – the folder you want to save the sequence and all its dependencies in.

Returns The full path to the main sequence file.

Raises `niveristand.errors.TranslateError` – if the function is not successfully translated.

9.3.6 Legacy API

This module describes the functionality equivalent to the deprecated IronPython API.

class `niveristand.legacy.NIVeriStand.Workspace`

Interface that controls the running state of the system and accesses the channels in the system.

GetAliasList()

Acquires all the aliases of a system.

GetChannelVectorValues (*name*)

Acquires the vector value of the channel you specify.

GetEngineState()

Returns the current state of the system.

GetMultipleChannelValues (*names*)

Acquires values from the channels you specify.

GetMultipleSystemNodesData (*names*)

Acquires data from the nodes you specify.

GetSingleChannelValue (*name*)

Acquires the value of the channel you specify.

GetSystemNodeChannelList (*name*)

Acquires all channels of the node you specify.

If you want to acquire all the channels in the system, enter "" as the node name.

GetSystemNodeChildren (*name*)

Acquires a list of all the child nodes nested under the node you specify.

LockWorkspaceFile (*old_password*, *new_password*)

Locks the configuration that is currently running.

This function will only succeed if a configuration is currently running. If this configuration was locked previously, you must enter the previous password in *old_password*.

RunWorkspaceFile (*file*, *launchworkspacewindow*, *deploysystemdefinition*, *timeout*, *username*, *password*)

Runs the workspace configuration file you specify.

Raises an error if you call this function while a configuration is already running. You must stop all running configurations before you call this function. If this function times out, check to see if the deployment process took longer than expected and caused the operation to timeout. Use the `GetEngineState` function to check the status of the system.

SetChannelVectorValues (*name*, *values*)

Sets the starting parameter vector value for the channel you specify.

The value you specify in *values* must be a matrix data type.

SetMultipleChannelValues (*names, values*)

Sets the value(s) for the channels you specify.

SetSingleChannelValue (*name, value*)

Sets the value for the channel you specify.

StopWorkspaceFile (*password*)

Stops the execution of the currently running configuration.

UnlockWorkspaceFile (*password*)

Unlocks the currently running configuration.

class niveristand.legacy.NIVeriStand.**Workspace2** (*gatewayIPAddress=None*)

Interface that controls the running state of the system and accesses the channels in the system.

ConnectToSystem (*systemdefinition_file, deploy, timeout*)

Connects the VeriStand Gateway to one or more targets running on the System Definition file you specify.

DisconnectFromSystem (*password, undeploy_system_definition*)

Disconnects the VeriStand Gateway from the targets.

GetSystemState ()

Returns the current state of the system.

LockConnection (*old_password, new_password*)

Locks the current VeriStand Gateway connection.

If the connection was locked previously, you must enter the previous password in *old_password*.

SetChannelValues (*channels, newValues*)

Sets the value for the channels you specify.

The *newValues* parameter accepts scalar, vector, and matrix data types.

StartDataLogging (*configuration_name, logInfo*)

Starts logging data to the configuration you specify.

StopDataLogging (*configuration_name*)

Terminates data logging for the configuration you specify.

UnlockConnection (*password*)

Unlocks the current VeriStand Gateway connection.

class niveristand.legacy.NIVeriStand.**PyAlarmPriority**

Priority of an alarm.

class niveristand.legacy.NIVeriStand.**PyAlarmState**

State of an alarm in the engine.

class niveristand.legacy.NIVeriStand.**PyAlarmMode**

Specifies the mode of an alarm when triggered.

Normal mode - triggers the alarm and runs the associated script. Indicate mode - only triggers the alarm.

class niveristand.legacy.NIVeriStand.**Alarm**(*name*, *target=None*, *gatewayIPAddress=None*)
Interface that queries information on a configured alarm.

GetAlarmData(*timeout*)
Acquires the alarm data.

SetAlarmData(*alarmDict*)
Sets the alarm data.

DEPRECATED function. This function does not support the Priority Number field. Use SetAlarmData2() instead.

SetAlarmData2(*alarmDict*)
Modifies an alarm in the system.

SetAlarmMode(*mode*)
Changes the mode of this alarm. See PyAlarmMode for possible values.

SetEnabledState(*enabled*)
Enables or disables the current alarm.

class niveristand.legacy.NIVeriStand.**AlarmManager**
Interface that acquires information on the state of the server alarm.

GetAlarmList()
Acquires a list of names of all the alarms configured in the system.

GetAlarmsStatus()
Acquires a list of alarms organized by status (high, medium, and low).

GetMultipleAlarmsData(*alarms*, *timeout*)
Acquires information about a list of alarms.

class niveristand.legacy.NIVeriStand.**AlarmManager2**(*gateway_ip_address=None*)
Interface that acquires information on the state of the server alarm.

GetAlarmList(*target*)
Acquires a list of names of all the alarms configured in the system.

GetAlarmsStatus(*target*)
Acquires a list of alarms organized by status (high, medium, and low).

GetMultipleAlarmsData(*target*, *alarms*, *timeout*)
Acquires information about a list of alarms.

class niveristand.legacy.NIVeriStand.**PyModelState**
Represents the state of a model.

class niveristand.legacy.NIVeriStand.**PyModelCommand**
Changes the state of the model.

class niveristand.legacy.NIVeriStand.**Model**(*name*, *target=None*, *gatewayIPAddress=None*)
Interface that acquires information on a specific model running on the system.

GetModelExecutionState ()

Acquires the execution time and state of the model.

RestoreModelState (*filepath*)

Restores the state of a model running on the target. Specify the path to the model file in *filepath*.

SaveModelState (*filepath*)

Saves the current model state to the path on the target you specify in *filepath*.

SetModelExecutionState (*command*)

Changes the current state of the model on the server.

This is a request operation on the server. Even if this function executes successfully, the model state may remain unchanged in some cases. See PyModelState for command values.

class niveristand.legacy.NIVeriStand.**ModelManager**

Interface that queries information on the models configured in the system.

GetModelList ()

Returns a list of all models configured in the system.

GetMultipleParameterValues (*names*)

Acquires the value(s) of the parameters you specify.

GetParameterVectorValues (*name*)

Acquires the vector values of the parameter you specify.

GetParametersList ()

Returns a list of all parameters in the system.

GetSingleParameterValue (*name*)

Acquires the value of the parameter you specify.

SetMultipleParameterValues (*names, values*)

Sets the value(s) of the parameters you specify.

SetParameterVectorValues (*name, values*)

Sets a vector value for a parameter.

The value you specify in *value* must be a matrix data type.

SetSingleParameterValue (*name, value*)

Sets the value of the parameter you specify.

class niveristand.legacy.NIVeriStand.**ModelManager2** (*gateway_ip_address=None*)

Interface that queries information on the models configured in the system.

GetModelList (*target*)

Returns a list of models on the target you specify.

GetMultipleParameterValues (*target, names*)

Acquires the value(s) of the parameters you specify.

GetParameterVectorValues (*target, name*)

Acquires the vector values of the parameter you specify.

GetParametersList (*target*)

Returns a list of all parameters in the target you specify.

GetSingleParameterValue (*target, name*)

Acquires the value of the parameter you specify.

SetMultipleParameterValues (*target, names, values*)

Sets the value of the parameter(s) you specify.

SetParameterValues (*target, names, matrixArr*)

Sets the vector value of the parameter(s) you specify.

The value you specify in *matrixArr* must be a matrix data type. Sample usage `ModelManager2.SetParameterValues("target1",["1By3Param","2By3Param"],[[[1,2,3]],[[1,2,3],[4,5,6]])`

SetParameterVectorValues (*target, name, values*)

Set a parameter vector values.

Values are expected to be a matrix type.

SetSingleParameterValue (*target, name, value*)

Sets the value of the parameter you specify.

UpdateParametersFromFile (*target, parameterfiles*)

Update a set of parameters specified in the parameter files.

class `niveristand.legacy.NIVeriStand.ChannelFaultManager` (*gatewayIPAddress=None*)

Interface that institutes software value forcing on the system.

ClearAllFaults ()

Clears all faults.

ClearFault (*name*)

Removes the channel you specify from the fault list.

GetFaultList ()

Acquires a list of all currently faulted channels.

GetFaultValue (*name*)

Acquires the fault value of a channel you specify.

SetFaultValue (*name, value*)

Sets the fault value of the channel you specify.

class `niveristand.legacy.NIVeriStand.PyStimulusState`

Represents the state of the stimulus generation server.

class `niveristand.legacy.NIVeriStand.PyStimulusResult`

Represents the result of the stimulus generation.

class `niveristand.legacy.NIVeriStand.Stimulus`

GetStimulusProfileFile ()

Acquires the current stimulus definition file.

GetStimulusProfileManagerState ()

Returns the state of the stimulus generation component.

GetStimulusProfileResult ()

Acquires the result of stimulus generation test.

Only the table test produces a test file of the result.

ReserveStimulusProfileManager ()

Creates a task that reserves the stimulus generation server.

This task prevents other clients from interrupting the stimulus generation process.

RunStimulusProfile (testfile, baselogpath, timeout, autostart, stopondisconnect)

Starts the stimulus generation you defined in the test file.

StopStimulusProfile ()

Stops the stimulus generation.

UnreserveStimulusProfileManager ()

Destroys the task that reserves the stimulus generation server. Frees the server for other clients to use.

class niveristand.legacy.NIVeriStand.**Stimulus2** (*gatewayIPAddress=None*)

Automates the execution of stimulus profiles.

RunStimulusProfile (testfile, baselogpath, timeout, autostart, stopondisconnect, parameterfiles=())

Starts the stimulus generation you defined in the test file.

class niveristand.legacy.NIVeriStand.**MacroRecorder**

class niveristand.legacy.NIVeriStand.**PyMacroPlayerState**

Represents the state of the macro player.

class niveristand.legacy.NIVeriStand.**PyMacroPlayerMode**

Represents the replay mode of the macro player.

class niveristand.legacy.NIVeriStand.**MacroPlayer** (*gatewayIPAddress=None*)

LoadMacro (file)

Loads a workspace macro.

PlayMacro (mode)

Replays the loaded macro.

PlayState ()

Acquires the current play state.

9.4 Restrictions

The following section contains a list of all restrictions inside a function using the `nivs_rt_sequence` decorator. If you violate any of the following rules, a `TranslateError` occurs.

9.4.1 Assignment

- To assign values to an existing variable, you must use the *value* property of the object.

```
int_var = I32Value(0)
int_array_var = I32ValueArray([1, 2, 3])
# Invalid value assignments
int_var = 5
int_array_var = [2, 3, 4]
int_array_var[2] = 5
# Valid value assignments
int_var.value = 5
int_array_var.value = [2, 3, 4]
int_array_var[2].value = 5
```

- Redefining a variable is not allowed.

```
int_var = I32Value(0)
int_var = DoubleValue(1.0) # The variable is already defined.
```

9.4.2 Conditional

- *If* statements only allow for boolean checks. You cannot use numbers, numeric data type declarations, or numeric variables inside *If* statements.

```
# Invalid conditions
int_var = I32Value(0)
if 1:
    if I32Value(0):
        if int_var.value:
# Valid conditions
bool_var = BooleanValue(True)
if True:
if False:
if BooleanValue(True):
if bool_var.value
```

- You cannot use numeric constants or data type declarations inside *If* expressions.

```
# Invalid conditions
int_var = I32Value(0)
int_var.value = 1 if 1 else 2
int_var.value = 1 if DoubleValue(1) else 2
int_var.value = 1 if int_var.value else 2
# Valid conditions
bool_var = BooleanValue(True)
int_var.value = 1 if True else 2
int_var.value = 1 if BooleanValue(True) else 2
int_var.value = 1 if bool_var.value else 2
```

9.4.3 Data Types

- Vector channel references will only work when you run sequences deterministically.
- **Channel references are the only data type declarations you can initialize with strings. All other data type declarations must be initialized with integers.**
 - Note: The BooleanValue data type is an exception to this rule. You can initialize BooleanValue with 'true' 'false' 'True' and 'False'.

```
# Invalid variable declarations
bool_var = BooleanValue("string")
double_var = DoubleValue("3.0")
int32_var = I32Value("1")
int64_var = I64Value("1")
uint32_var = U32Value("1")
uint64_var = U64Value("1")
bool_array_var = BooleanValueArray([True, "False"])
double_array_var = DoubleValueArray([3.0, 5.0, "6.0"])
int32_array_var = I32ValueArray([1, 2, "3"])
int64_array_var = I64ValueArray([1, 2, "3"])
uint32_array_var = U32ValueArray([1, 2, "3"])
uint64_array_var = U64ValueArray([1, 2, "3"])
```

- Signed integers cannot use the full range of values.

```
int32_invalid_var = I32Value(0xFFFFFFFF)
int32_last_valid_var = I32Value(0x7FFFFFFF)
int64_invalid_var = I64Value(0xFFFFFFFFFFFFFFFF)
int64_last_valid_var = I64Value(0x7FFFFFFFFFFFFFFF)
```

9.4.4 Error Generation

- When you generate an error, you can only use integer constants for the error code parameter, strings for the error message parameter, and ErrorAction members as the error action parameter.

```
# Valid statement
generate_error(-1, "My error", ErrorAction.AbortSequence)
# Invalid statements
int_var = I32Value(-1)
generate_error(int_var.value, "My error", ErrorAction.
    ↳AbortSequence)
generate_error(-1, 2, ErrorAction.AbortSequence)
generate_error(-1, "My error", 3)
```

9.4.5 Functions

Built-in Math Functions

- You cannot pass down an NI VeriStand data type directly as a parameter of the built-in math functions. As an alternative, you can pass a variable or data type declaration to these functions using the *value* property.

```
int_var = I32Value(-1)
# Invalid usage
int_var.value = abs(I32Value(-1))
# Valid usages
int_var.value = abs(I32Value(-1).value)
int_var.value = abs(int_var.value)
```

- BooleanValue for *abs* behaves differently between Python and Stimulus Profile Editor.

```
bool_var = BooleanValue(-5)
bool_var.value = abs(bool_var.value)
return bool_var.value # This returns False in the Stimulus_
↩Profile Editor but returns True in Python.
```

Built-in VeriStand Functions

- Some of these functions are not implemented in Python. Please refer to [Library](#) for more information.

9.4.6 Function Definitions

- You cannot define new functions inside an *if* block, a loop, or a task.
- The **args* and *kwargs* variables are not supported.

9.4.7 Loops

- For Loops do not support:**
 - else* blocks
 - ranges with a start value
 - ranges with a step value
 - ranges that use a channel reference
 - ranges that use array constants

```
# The following statements are invalid:
for x in range(5):
    pass
else:
    pass
for x in range(2, 5):
```

(continues on next page)

(continued from previous page)

```
for x in range(2, 5, 2):
    channel_ref = ChannelReference('Aliases/DesiredRPM')
for x in range(channel_ref.value):
    for x in [1, 2, 3]:
```

- **While Loops do not support:**

- using *else* blocks
- using a numeric constant as the condition
- using *break* statements

```
# The following statements are invalid:
int_var = I32Value(5)
while 1:
while int_var:
while int_var.value:
while True:
    pass
else:
    pass
while True:
    break
```

9.4.8 Operators

Add

- You cannot use several pluses one after another. Always use one plus sign. If you violate this rule, a *TranslateError* occurs.

```
int_var = I32Value(0)
int_var.value = 1 +++ 2 # This is not supported.
int_var.value = 1 + 2 # Always use a single plus.
```

Arithmetic Shift

- You cannot use double data types to the left of an arithmetic shift operation in Python.

```
double_var = DoubleValue(5.0)
# The following statements only work when the code is run_
↳deterministically.
double_var.value = DoubleValue(3.0) << 5
double_var.value = 3.0 >> 5
double_var.value = double_var.value >> 5
```

- You cannot use double or boolean data types to the right of an arithmetic shift operation.

```
bool_var = BooleanValue(True)
bool_var.value = 5 >> BooleanValue(True)
bool_var.value = 5 << True
bool_var.value = 5 << bool_var.value
double_var = DoubleValue(5.0)
double_var.value = 5 >> DoubleValue(3.0)
double_var.value = 5 << 3.0
double_var.value = 5 << double_var.value
```

- You cannot use a negative number to the right of an arithmetic shift operation. As an alternative, use the opposite operation with a positive value.

```
int_var = I32Value(1)
int_var.value = int_var.value >> -2 # This is not allowed.
int_var.value = int_var.value << 2 # Use this instead.
```

Bitwise Operators

- You cannot use bitwise operations on float or boolean values in Python.

```
bool_var = BooleanValue(False)
double_var = DoubleValue(1.0)
# The following statements only work when the code is run
↳ deterministically.
bool_var.value = BooleanValue(True) & BooleanValue(True)
double_var.value = 3.5 | 2.5
double_var.value = DoubleValue(3.5) ^ DoubleValue(2.5)
```

Comparison Operators

- You cannot use cascading comparison operators. Only use one comparison operator at a time.

```
int_var = I32Value(0)
int_var.value = 1 == 2 == 3 == 4 # This is not allowed.
```

Logical Operators

- Logical operators only accept boolean values.
- You cannot use cascading logical operators. Only use one logical operator at a time.

Unary Invert

- The unary inversion operator (~) only accepts integer values.

9.4.9 Parameters

- If you need to pass an immutable object (such as the *value* property of an NI VeriStand data type) by reference, you must run your code deterministically. Otherwise, the parameter will not actually pass by reference when you run the code in Python.

```
@NivsParam('param', DoubleValue(0), NivsParam.BY_REF)
@nivs_rt_sequence
def _increment_by_ref(param):
    param.value += 1
    return param.value

@nivs_rt_sequence
def call_increment_by_ref():
    int_var = I32Value(1)
    _increment_by_ref(int_var.value)
    return int_var.value # This will return 1 in Python and 2 in
↳the Stimulus Profile Editor.
```

9.4.10 Return Statements

- A function can only have a single return statement and it has to be the last line of the function.
- You cannot use return statements inside an *if* block, a *try* block, a *finally* block, a loop, a multitask, or a task.
- Return statements can only return scalar values through the *value* property.

```
int_var = I32Value(1)
int_array_var = I32ValueArray([1, 2, 3])
# Invalid return statements
return int_var
return int_array_var
return DoubleValueArray[1.0, 2.0]
# Valid return statements
return int_var.value
return int_array_var[0].value
```

9.4.11 Tasks

- You cannot create more than one task with the same name.

```
with multitask() as mt:
    @task(mt)
    def f1():
        pass
    @task(mt)
    def f1(): # Task with the same name already exists.
        pass
```

- You cannot create parameters for tasks or multitasks.

```
with multitask(param) as mt: # Parameter not allowed.  
    @task(mt)  
    def f1(param_task): # Parameter not allowed.
```

9.4.12 Try

- *Try* is only allowed to be the first statement of a function.
- **You cannot use a *try* statement within:**
 - another *try* statement
 - an *if* block
 - an *else* block
 - a loop
 - a task
 - a multitask
- You cannot use a *try* statement with *except* or *orelse*.

9.4.13 Yield

- You cannot use *yield* as an operator or parameter.

CHAPTER 10

Indices and tables

- `genindex`
- `modindex`
- `search`
